KLEYM / QA REVIEW
Results and remaining release gates

26 October 2026 | Source, desktop, responsive and Android emulator proof

The new plan is ready; complete application/Mainnet sign-off is not yet granted. The preflight combined current CI evidence, new source regressions, hosted page checks and a newly configured Android Studio emulator. Those UI checks generated no recovery phrase, sent no email and moved no assets. A subsequent standalone protocol run used fresh Friendbot-funded Testnet accounts and a disposable custom issuer; its results are separated below.

Build and proof boundaries

- Hosted browser/emulator observations: 4b5f29920383d3730f81cd4c9633a581b4ae29ae on the team's Testnet deployment.

- Source fixes and new plan candidate: b842fe3 (full SHA in evidences/case-specs.json). No transaction builder, wallet-signature rule or Mainnet enablement changed.

- Existing desktop/physical Android EMAIL claim proof remains in docs/reviews/2026-10-26/freighter-readiness, tied to its original build. It is not copied as a new emulator or full-plan pass.

Actually checked

Check	Result	Scope
Latest baseline develop CI	All four jobs succeeded	Real PostgreSQL/Redis lifecycle, permissions, concurrency, reclaim, SSO/MFA, backup, SDK/webhooks, Chromium export gate and build/audit; exact job steps in evidences/develop-ci.json
Patched source regression suite	943 passed / 90 files / 0 failed	Vitest, two workers, 58.44 seconds
New regression checks	Two prepatch failures; three postpatch passes	Missing reminder eligibility, honest passkey boundary, qualified legacy reminder compatibility
TypeScript, ESLint, production build	Passed	Node 24.22.1 / Next.js 16.4.3
Fresh production audit	0 vulnerabilities	Registry audit snapshot; not an independent security audit
Fresh standalone Testnet protocol matrix	7/7 passed; 22 successful transactions	New/existing recipient × XLM/custom token; exact credits, account cleanup, reserve recovery, excess-signature refusal and both expiry predicates. Disposable Node signers/custom issuer, not official Circle USDC or Freighter acceptance. Public evidence in evidences/runs/release-733d5e1/protocol-matrix.json
Hosted scoped smoke	34 named observations passed	Thirteen authenticated routes at desktop and 360px, plus menu, input, manual balance lookup and native emulator observations; not all controls or full case steps
Android Studio emulator	Android 16 / API 36.1 booted; Chrome 134.0.6998.135	Login, dashboard, campaign screen, phone-wallet button/manual address fallback, header-to-Settings navigation, password-field layout and logout observed
Plan artifact validation	373 unique cases, 24 pages, 121 API methods, 296 static controls, 17 claim states	All catalog rows initially Not Run; workbook reopened; every case ID found in PDF; all 122 PDF pages rendered with no text outside margins

The authenticated routes checked were Dashboard, Campaigns, Templates, Approvals, History, Settings, second-factor settings and all six admin pages. Each loaded with a heading, no application-error screen and no page-wide horizontal overflow at the measured sizes. At 360px, password fields measured 287 × 49 CSS pixels. Invalid funding account/negative amount kept Continue disabled; the manual public-address lookup showed 16 test USDC and zero XLM. Review displayed three links, total three USDC, three XLM reserve and the expected fee bid before any keys were generated.

Defects fixed during this review

1. KLM-QA-20261026-01 — P2 usability: new local-link campaigns exposed email-reminder choices despite having no invitation-delivery path. Creator reminder controls now require the qualified legacy Testnet mode; new local/OTP campaigns explain private sharing and deadlines. Existing historical reminder behavior is preserved.

2. KLM-QA-20261026-02 — P1 misleading security copy: the passkey option claimed later link copies were useless. It now states that passkey verification is a Kleym application check, not an added Stellar signature, and recommends assigned-wallet claims for an on-chain wallet lock.

The initial failure and corrected behavior are covered by tests/lib/campaign/recipient-controls.test.ts. PR #142 merged into develop as 733d5e14faa3b03742f3942208d790ece1486dc3, with all four checks passed. An Ubuntu font-mirror stall was cancelled and the browser job passed on a fresh runner with unchanged test requirements. Hosted retest/deployment results belong in the release follow-up evidence, rather than being inferred from source tests. The tested application sources match the merge; later differences are QA documentation and evidence.

At an earlier 26 October deployment observation, the new web image was still publishing and its status was BUILDING. The existing app returned health/readiness 200, but still displayed the old controls. At that point the fixes were merged and source-tested, not yet verified live. The landing update had succeeded and the worker update was still deploying. No deployment region was changed and no success was inferred from the older healthy replica.

Later checkpoint verification: all three PR #142 deployments reached SUCCESS at the exact merge commit. An authenticated hosted retest then confirmed zero unavailable reminder checkboxes, the new private-sharing guidance, and removal of the false passkey promise. See evidences/runs/release-733d5e1/hosted-controls.json and its screenshot. The earlier pending-publication observation is preserved as history; these two fixes are now verified live. This does not qualify the remaining full release matrix or enable Mainnet.

Remaining qualification

- The 373-case catalog is an execution plan, not 373 completed tests. Full conditional controls, every role/state combination, all invalid field matrices and the fresh full wallet lifecycle matrix still need case-by-case evidence. The 34 narrow observations and 943 unit assertions must not be added together as equivalent user journeys.

- Official Freighter installation in the emulator requires private Play Store authentication; the operator has agreed to install it. No official v1.26.29 APK asset was available at the inspected GitHub release; no mirror or unreviewed developer preview was installed. The image's Chrome 134 is a compatibility observation, not qualification of the current supported Chrome release. Update through Google Play. The emulator was logged out, reopened for private installation and gracefully stopped again when the user deferred work until tomorrow. Its persistent disk and Android Studio registration were verified; installation/version remain unverified.

- Physical OEM app return/backgrounding, secure hardware/biometrics, current production Freighter signing and fresh fund/claim/reclaim combinations are not replaced by viewport emulation. No physical USB phone is needed for routine emulator browser checks.

- Mainnet stays disabled. Separate approved domain/deployment/keys/queues, sponsor and treasury capital/ownership, real alert delivery, populated restore/rollback proof, sender authentication/provider tracking confirmation and explicit real-asset qualification remain release gates. No arbitrary global campaign-USDC cap is introduced.

- Lantern remains deferred pending its approved curated build. Optional SSO, SCIM, compliance/conversion and operational providers require their configured isolated fixtures and the appropriate sign-off; a generic page load does not prove those external systems.

See docs/android-qa.md for Android Studio start/stop instructions. All supporting JSON, screenshots, generators and layout renders are under evidences/. Private credentials, codes, keys, recipient CSVs and full claim URLs are excluded.
